Add WeChat edu\_assist\_pro

## Chapter 10 - Declaring Types and Classes

# Type Declarations

In Haskell, a new name for an existing type can be defined using a type declaration.

Assignment Project Exam Help

<https://eduassistpro.github.io/>

`type String = [Char]` Add WeChat edu\_assist\_pro

String is a synonym for the type [Char].

Type declarations can be used to make other types easier to read. For example, given

```
type Pos = (Int,Int)
```

Assignment Project Exam Help

we can define:

<https://eduassistpro.github.io/>

Add WeChat edu\_assist\_pro

```
origin  :: Pos  
origin  = (0,0)  
  
left    :: Pos → Pos  
left (x,y) = (x-1,y)
```

Like function definitions, type declarations can also have parameters. For example, given

```
type Pair a = (a,a)
```

Assignment Project Exam Help

we can define:

<https://eduassistpro.github.io/>

Add WeChat edu\_assist\_pro

```
mult    :: Pair Int → Int
mult (m,n) = m*n

copy    :: a → Pair a
copy x  = (x,x)
```

Type declarations can be nested:

```
type Pos = (Int,Int)
```

```
type Trans = Pos -> Pos
```

<https://eduassistpro.github.io/>

Add WeChat edu\_assist\_pro

However, they cannot be recursive:

```
type Tree = (Int,[Tree])
```

# Data Declarations

A completely new type can be defined by specifying its values using a data declaration.

Assignment Project Exam Help

<https://eduassistpro.github.io/>

`data Bool = False | True`

Bool is a new type, with two new values False and True.

Note:

- ❓ The two values False and True are called the constructors for the type Bool.
- ❓ Type and constructor names must begin with an upper-case letter.
- ❓ Data declarations are similar to context free grammars. The former specifies the values of a type, the latter specifies the language.

Assignment Project Exam Help

<https://eduassistpro.github.io/>

Add WeChat edu\_assist\_pro

Values of new types can be used in the same ways as those of built in types. For example, given

```
data Answer = Yes | No | Unknown
```

we can define:

Assignment Project Exam Help

<https://eduassistpro.github.io/>

```
answers    :: [Answer]
answers    = [Yes, No, Unknown]

flip      :: Answer → Answer
flip Yes  = No
flip No   = Yes
flip Unknown = Unknown
```

The constructors in a data declaration can also have parameters. For example, given

```
data Shape = Circle Float  
           | Rect Float Float
```

Assignment Project Exam Help

we can define:

<https://eduassistpro.github.io/>

Add WeChat edu\_assist\_pro

```
square      :: Float → Shape  
square n    = Rect n n  
  
area        :: Shape → Float  
area (Circle r) = pi * r^2  
area (Rect x y) = x * y
```

Note:

- ❓ Shape has values of the form Circle r where r is a float, and Rect x y where x and y are floats.
- ❓ Circle and Rect can be viewed as functions that construct values of type Shape:

Assignment Project Exam Help

<https://eduassistpro.github.io/>

Add WeChat edu\_assist\_pro

```
Circle :: Float → Shape
```

```
Rect   :: Float → Float → Shape
```

Not surprisingly, data declarations themselves can also have parameters. For example, given

```
data Maybe a = Nothing | Just a
```

we can define:

Assignment Project Exam Help

<https://eduassistpro.github.io/>

```
safediv  :: Int -> Int -> Maybe Int
safediv _ 0 = ?
safediv m n = ?

safehead :: [a] -> Maybe a
safehead [] = ?
safehead xs = ?
```

# Recursive Types

In Haskell, new types can be declared in terms of themselves. That is, types can be recursive.

Assignment Project Exam Help

<https://eduassistpro.github.io/>

data Nat = Zero | Succ

Add WeChat edu\_assist\_pro

Nat is a new type, with constructors  $\text{Zero} :: \text{Nat}$  and  $\text{Succ} :: \text{Nat} \rightarrow \text{Nat}$ .

Note:

-  A value of type `Nat` is either `Zero`, or of the form `Succ n` where  $n :: \text{Nat}$ . That is, `Nat` contains the following infinite sequence of values:

Assignment Project Exam Help

Zero

<https://eduassistpro.github.io/>

Add WeChat edu\_assist\_pro

Succ Zero

Succ (Succ Zero)

•  
•  
•

? We can think of values of type Nat as natural numbers, where Zero represents 0, and Succ represents the successor function 1+.

? For example, the value

Assignment Project Exam Help

<https://eduassistpro.github.io/>

Succ (Succ (Succ Zero))

Add WeChat edu\_assist\_pro

represents the natural number

$1 + (1 + (1 + 0))$

=

3

Using recursion, it is easy to define functions that convert between values of type Nat and Int:

```
nat2int
```

Assignment Project Exam Help  
::

```
nat2int = ?
```

<https://eduassistpro.github.io/>

Add WeChat edu\_assist\_pro

```
int2nat :: Int → Nat
```

```
int2nat = ?
```

Two naturals can be added by converting them to integers, adding, and then converting back:

```
add  :: Nat → Nat → Nat  
add m n = int2nat (nat2int m + nat2int n)
```

<https://eduassistpro.github.io/>

Add WeChat edu\_assist\_pro

However, using recursion the function add can be defined without the need for conversions:

```
add Zero    n = n  
add (Succ m) n = Succ (add m n)
```

Two naturals can be added by converting them to integers, adding, and then converting back:

```
add  :: Nat → Nat → Nat  
add m n = int2nat (nat2int m + nat2int n)
```

<https://eduassistpro.github.io/>

Add WeChat edu\_assist\_pro

However, using recursion the function add can be defined without the need for conversions:

```
add m n = ?
```

For example:

$$\begin{aligned} & \text{add (Succ (Succ Zero)) (Succ Zero)} \\ = & \text{Succ (add (Succ Zero) (Succ Zero))} \\ = & \text{Succ (Succ (Succ Zero))} \\ = & \text{Succ (Succ (Succ Zero))} \end{aligned}$$

Assignment Project Exam Help  
<https://eduassistpro.github.io/>  
Add WeChat edu\_assist\_pro

Note:

-  The recursive definition for add corresponds to the laws  $0+n = n$  and  $(1+m)+n = 1+(m+n)$ .

# Arithmetic Expressions

Consider a simple form of expressions built up from integers using addition and multiplication.

Assignment Project Exam Help

<https://eduassistpro.github.io/>

Add WeChat edu\_assist\_pro

Using recursion, a suitable new type to represent such expressions can be declared by:

```
data Expr = Val Int  
          | Add Expr Expr  
          | Mul
```

Assignment Project Exam Help

<https://eduassistpro.github.io/>

Add WeChat edu\_assist\_pro

For example, the expression on the previous slide would be represented as follows:

```
Add (Val 1) (Mul (Val 2) (Val 3))
```

Using recursion, it is now easy to define functions that process expressions. For example:

Assignment Project Exam Help  
<https://eduassistpro.github.io/>  
Add WeChat edu\_assist\_pro

```
size      :: Expr  
size = ?  
  
eval      :: Expr → Int  
eval = ?
```

Note:

? The three constructors have types:

$\text{Val} :: \text{Int} \rightarrow \text{Expr}$

$\text{Add} :: \text{Expr} \rightarrow \text{Expr} \rightarrow \text{Expr}$

$\text{Mul} :: \text{Expr} \rightarrow \text{Expr} \rightarrow \text{Expr}$

<https://eduassistpro.github.io/>  
Add WeChat edu\_assist\_pro

? Many functions on expressions can be defined by replacing the constructors by other functions using a suitable fold function. For example:

Exercise: Define fold!

$\text{eval} = \text{fold id } (+) (*)$

# Binary Trees

In computing, it is often useful to store data in a two-way branching structure or binary tree.

Assignment Project Exam Help

<https://eduassistpro.github.io/>

Add WeChat edu\_assist\_pro

Using recursion, a suitable new type to represent such binary trees can be declared by:

```
data Tree a = Leaf a  
            | Node (Tree a) a (Tree a)
```

Assignment Project Exam Help

<https://eduassistpro.github.io/>

Add WeChat edu\_assist\_pro

For example, the tree on the previous slide was presented as follows:

```
t :: Tree Int  
t = Node (Node (Leaf 1) 3 (Leaf 4)) 5  
        (Node (Leaf 6) 7 (Leaf 9))
```

We can now define a function that decides if a given value occurs in a binary tree:

```
occurs :: Ord a => a -> Tree a -> Bool
```

```
occurs x t = ?
```

<https://eduassistpro.github.io/>

Add WeChat edu\_assist\_pro

But... in the worst case, when the value does not occur, this function traverses the entire tree.

Now consider the function flatten that returns the list of all the values contained in a tree:

flatten

flatten t = ?

Assignment Project Exam Help  
:: Tree a → [a]

<https://eduassistpro.github.io/>

Add WeChat edu\_assist\_pro

A tree is a search tree if it flattens to a list that is ordered. Our example tree is a search tree, as it flattens to the ordered list [1,3,4,5,6,7,9].

Search trees have the important property that when trying to find a value in a tree we can always decide which of the two sub-trees it may occur in:

occurs  $x \ t = ?$

Assignment Project Exam Help

<https://eduassistpro.github.io/>

Add WeChat edu\_assist\_pro

This new definition is more efficient, because it only traverses one path down the tree.

# Exercises

- (1) Using recursion and the function add, define a function that multiplies two natural numbers.

Assignment Project Exam Help

- (2) Define a suitable function <https://eduassistpro.github.io/> and give a few examples use.  
Add WeChat edu\_assist\_pro

- (3) A binary tree is complete if the two sub-trees of every node are of equal size. Define a function that decides if a binary tree is complete.
